DEC 9, 2009

BRAD NEWTON, SAIC FALL GROUNDWATER LEVEL UPDATE

ITEM

Presentation of the fall groundwater index for the Nipomo Mesa area.

BACKGROUND

Brad Newton of SAIC is scheduled to summarize the attached report. The report is an independent product of SAIC and is not reviewed or recognized by the Nipomo Mesa Management Area Technical group.

FISCAL IMPACT

Development of this draft did use previously budgeted staff time.

RECOMMENDATION

Staff recommends that the Board receive the Report and give direction to staff.

RE: Fall 2009 Groundwater Index

DATE: December 01, 2009

INTRODUCTION

Groundwater surface elevations (GSE) underlying the Nipomo Mesa are regularly measured at many places (wells) across the mesa. The Fall 2009 Groundwater Index (GWI) has been estimated and presented herein along with historical GWI from 1975 to present based on these groundwater surface elevation measurements collected during spring and fall across the Nipomo Mesa. Limited measurements of GSE were available for the years 1982, 1983, 1984, 1994 and 1997, thus precluding a reliable estimate of GWI for those years.

Ground elevation surveys for the key wells were conducted in preparation of the 1st Annual Report - Calendar Year 2008 for the Nipomo Mesa Management Area (NMMA). These updated reference points were not incorporated into the GWI to preserve consistency in the historical calculations and presentations.

The NMMA Technical Group has not reviewed this technical memorandum, its findings, or any presentation of this evaluation.

RESULTS

Estimated Fall 2009 GWI is 59,000 acre-feet (AF), which is 6,000 AF less than Fall 2009 (Table 1, Figure 1). The Key Well Index from NMMA 1st Annual Report Calendar Year 2008 generally follows the same historical trends as the GWI estimates (Figure 1).

METHODOLOGY

The annual estimates of Spring and Fall GWI are based on GSE measurements regularly made by San Luis Obispo County Department of Public Works (SLO DPW), NCSD, USGS, and Woodlands. The integration of GSE data is accomplished by using computer software to interpolate between measurements and calculate GWI within the principal production aquifer assuming an unconfined aquifer and a specific yield of 11.7 percent. Limited measurements of GSE were available for the years 1982, 1983, 1984, 1994 and 1997, precluding a reliable estimate of GWI for those years.

Groundwater Surface Elevation Measurements

Groundwater surface elevation data were obtained from SLO DPW, NCSD, USGS, and Woodlands. SLO DPW measures GSE in monitoring wells during the spring and the fall of

SAIC Engineering, Inc. A Subsidiary of Science Applications International Corporation

each year. Woodlands and NCSD measures GSE in their monitoring wells monthly. For the years 1975 to 1999, available representative GSE data were used to estimate GWI. For the years 2000 to 2009, only GSE data from the same 45 wells were used to estimate GWI.

The GSE data was reviewed in combination with well completion reports and historical hydrographic records in order to exclude measurements that do not accurately represent static water levels within the principal production aquifer. Wells that do not access the principal production aquifer or were otherwise determined to not accurately represent static water levels within the aquifer were not included in analysis.

Groundwater Surface Interpolation

The individual GSE measurements from each year were used to produce a GSE field by interpolation using the inverse distance weighting (IDW) method.

Groundwater Index

The value of the groundwater index was estimated for the boundary determined in Phase III of the trial. The GWI was estimated by subtracting both the mean sea level surface (elevation equals zero) and the volume of bedrock above sea level from the saturated volume. The bedrock surface elevation is based on Figure 11: Base of Potential Water-Bearing Sediments, presented in the report, Water Resources of the Arroyo Grande - Nipomo Mesa Area (DWR 2002). The bedrock surface elevation was preliminarily verified by reviewing driller reports obtained from DWR. The saturated volume above sea level was multiplied by a specific yield of 11.7% to estimate the recoverable amount of GWI. The specific yield is based on the average weighted specific yield for the Nipomo Mesa Hydrologic Sub-Area (DWR 2002, pg. 86).

Key Well Index

The NMMA Technical Group selected the data from eight inland key wells to represent the whole of the NMMA. The average spring groundwater elevation of these key wells is used to calculate the Key Wells Index.

The Key Well Index was calculated annually using Spring GSE measurements from 1975 to 2008. The Key Wells were selected to represent various portions of the groundwater basin within the NMMA. In selecting the eight key wells, the following criteria were applied so that the wells generally represent the NMMA as a whole:

(1) The wells are geographically distributed,

(2) No single well overly influences the Key Well Index.

The first criterion was met in the selection of the wells, such that no well represented a disproportionate area. To meet the second criterion, groundwater elevations from each well were normalized so that any well where elevations were on the average higher or lower than the other wells did not overly influence the magnitude of the Key Well Index. This

normalization was accomplished by dividing each spring groundwater elevation measurement by the sum of all the Spring GSE data for that well.

The Key Well Index was defined for each year as the average of the normalized spring groundwater data from each well. The lowest value of the Key Well Index could be considered the "historical low" within the NMMA.
